

Biology Study Notes

Photosynthesis is the process by which green plants convert sunlight into chemical energy.

Chlorophyll is the pigment inside chloroplasts that absorbs light most strongly in the blue and red

regions of the spectrum.

During the light dependent reactions water molecules are split and oxygen is released as a byproduct.

The Calvin cycle produces glucose by fixing carbon dioxide using ATP and NADPH from the light

reactions.

Mitochondria are organelles that generate ATP through cellular respiration in both plants and animals.

Osmosis is the movement of water across a semipermeable membrane from low to high solute

concentration.

Enzymes are biological catalysts that speed up reactions by lowering activation energy without being

consumed.

Deoxyribonucleic acid stores genetic information in the sequence of its four nitrogen bases.
